Introduction
Due to the dramatic measures accompanying isolation and the general uncertainty and fear associated with COVID-19, patients and relatives may be at high risk for adverse psychological outcomes. Until now there has been little research focusing on the prevalence and risk factors for psychological distress in COVID-19 patients and their relatives. The objective of our study was to prospectively assess psychological distress in COVID-19 patients and their relatives 30 days after hospital discharge.

Methods
In this prospective observational cohort study at two Swiss tertiary-care hospitals, we included consecutive adult patients hospitalized between March and June 2020 for a proven COVID-19 and their relatives. The primary outcome was psychological distress, defined as symptoms of anxiety and/or depression measured with the Hospital Anxiety and Depression Scale (HADS). A score of ≥8 on the depression and/or anxiety subscale was defined as psychological distress. The main secondary endpoint was symptoms of post-traumatic stress disorder (PTSD), defined as a score of ≥1.5 on the Impact of Event Scale-Revised (IES-R).

Results
Among 126 included patients, 24 (19.1%) had psychological distress and 10 (9.5%) had symptoms of PTSD 30 days after hospital discharge. In multivariable logistic regression analyses, three factors were independently associated with psychological distress in patients: lower resilience (OR 0.82, 95%CI 0.71 to 0.94, p=0.005), higher levels of perceived stress (OR 1.21, 95%CI 1.06 to 1.38, p=0.006) and low frequency of contact with relatives (OR 7.67, 95%CI 1.42 to 41.58, p=0.018). The model showed good discrimination with an area under the receiver-operating characteristic curve (AUC) of 0.92. Among 153 relatives, 35 (22.9%) showed symptoms of psychological distress, and three (2%) of PTSD. For relatives, resilience was also an independent protective factor (OR 0.85, 95%CI 0.75 to 0.96, p=0.007), whereas perceived overall burden caused by COVID-19 was an independent risk factor for psychological distress (OR 1.72, 95%CI 1.31 to 2.25, p<0.001). The overall model also had good discrimination, with an AUC of 0.87.

Conclusion
A relevant number of COVID-19 patients as well as their relatives exhibited psychological distress 30 days after hospital discharge. These results might aid in development of strategies to prevent psychological distress in COVID-19 patients and their relatives.
